1 Introduction

Given the opportunity to review the design document and related smart contract source code of the LeverFi protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About LeverFi

LeverFi is a decentralized leveraged trading platforms which offers a leveraged solution for traders. With the LeverFi platform, traders could deposit collateral such as BTC, ETH, Curve-LP, Uni-LP and more to trade changes in asset prices at up to 10x leverage. Collaterals are deposited to farming protocols, allowing traders to earn yields and leverage trade at the same time. The basic information of the LeverFi protocol is as follows:

1.2 About PeckShield

PeckShield Inc. [15] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

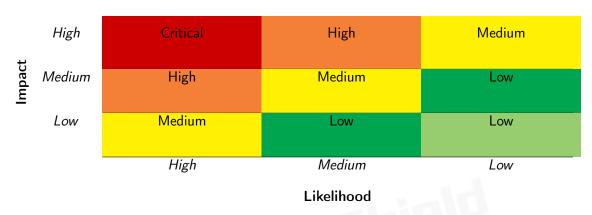

Table 1.2: Vulnerability Severity Classification

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [14]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the

Table 1.3: The Full List of Check Items

| Category | Check Item |

contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- <u>Basic Coding Bugs</u>: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [13], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

| Category | Summary |
|--------------------------------|---|
| Configuration | Weaknesses in this category are typically introduced during |
| | the configuration of the software. |
| Data Processing Issues | Weaknesses in this category are typically found in functional- |
| | ity that processes data. |
| Numeric Errors | Weaknesses in this category are related to improper calcula- |
| | tion or conversion of numbers. |
| Security Features | Weaknesses in this category are concerned with topics like |
| | authentication, access control, confidentiality, cryptography, |
| | and privilege management. (Software security is not security |
| | software.) |
| Time and State | Weaknesses in this category are related to the improper man- |
| | agement of time and state in an environment that supports |
| | simultaneous or near-simultaneous computation by multiple |
| Forman Canadiai ana | systems, processes, or threads. |
| Error Conditions, | Weaknesses in this category include weaknesses that occur if |
| Return Values, Status Codes | a function does not generate the correct return/status code, or if the application does not handle all possible return/status |
| Status Codes | codes that could be generated by a function. |
| Resource Management | Weaknesses in this category are related to improper manage- |
| Nesource Management | ment of system resources. |
| Behavioral Issues | Weaknesses in this category are related to unexpected behav- |
| Deliavioral issues | iors from code that an application uses. |
| Business Logics | Weaknesses in this category identify some of the underlying |
| Dusiness Togics | problems that commonly allow attackers to manipulate the |
| | business logic of an application. Errors in business logic can |
| | be devastating to an entire application. |
| Initialization and Cleanup | Weaknesses in this category occur in behaviors that are used |
| | for initialization and breakdown. |
| Arguments and Parameters | Weaknesses in this category are related to improper use of |
| | arguments or parameters within function calls. |
| Expression Issues | Weaknesses in this category are related to incorrectly written |
| | expressions within code. |
| Coding Practices | Weaknesses in this category are related to coding practices |
| | that are deemed unsafe and increase the chances that an ex- |
| | ploitable vulnerability will be present in the application. They |
| | may not directly introduce a vulnerability, but indicate the |
| | product has not been carefully developed or maintained. |

2 Findings

2.1 Summary

Here is a summary of our findings after analyzing the LeverFi implementation. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

| Severity | # of Findings |
|---------------|---------------|
| Critical | 3 |
| High | 0 |
| Medium | 2 |
| Low | 2 |
| Informational | 0 |
| Total | 7 |

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 3 critical-severity vulnerabilities, 2 medium-severity vulnerabilities, and 2 low-severity vulnerabilities.

ID Title Severity Category **Status** PVE-001 Critical **Business Logic** Possible Fund Stealing From Approving Fixed **PVE-002** Low Accommodation of approve() Idiosyn-Coding Practices Fixed crasies **PVE-003** Medium Trust Issue of Admin Keys Confirmed **Business Logics** PVE-004 Critical Necessity of Single-Shot Initialization of Time and State Fixed AaveReinvestmentLogic PVE-005 Time and State Low Reentrancy Risk in Ledger Fixed **PVE-006** Critical Manipulated Utilized Supply For Inflated Time and State Fixed Reserve Balance Business Logic PVE-007 Medium Exposure Permissioned Fixed Ledger::swapPosition()

Table 2.1: Key LeverFi Audit Findings

Besides recommending specific countermeasures to mitigate these issues, we also emphasize that it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms need to kick in at the very moment when the contracts are being deployed in mainnet. Please refer to Section 3 for details.

3 Detailed Results

3.1 Possible Fund Stealing From Approving Users

• ID: PVE-001

• Severity: Critical

• Likelihood: High

• Impact: High

• Target: ZeroexSwapAdapter

• Category: Business Logic [9]

• CWE subcategory: CWE-841 [6]

Description

To facilitate the token swap when an user executes trade in the LeverFi protocol, the ZeroexSwapAdapter contract has a helper routine swap(). This routine is developed to transfer user funds into this contract and then use an external router to swap the funds.

To elaborate, we show below the <code>swap()</code> routine implementation. This routine allows the user to provide an arbitrary <code>swapBytesData</code> which is parsed into <code>approveRouter</code>, <code>sellingAsset</code>, <code>buyingAsset</code>, and <code>swapBytes</code>. These parameters are directly used in <code>approveRouter.call(swapBytes)</code> (line 24). However, the arbitrary <code>approveRouter</code> and <code>swapBytes</code> may be exploited to transfer all funds from the users to the hacker.

Listing 3.1: ZeroexSwapAdapter::swap()

Specifically, the Ledger contract needs to give allowance to the ZeroexSwapAdapter contract to facilitate the token swap. To save gas fee, the ledger gives a maximum allowance as type(uint256).max to the ZeroexSwapAdapter contract! In this case, if the approveRouter value is changed to the token address and the swapBytes is encoded to call function token.transferFrom(ledgerAddress, hackerAddress, amount) where amount = token.balanceOf(ledgerAddress), all token of the Ledger contract would be withdrawn by the malicious actor.

```
66
       function executeTrade(
67
            mapping(address => DataTypes.ReserveConfig) storage reserveConfig,
68
            mapping(address => DataTypes.AssetConfig) storage assetConfig,
69
            mapping(address => DataTypes.UserPosition) storage userPosition,
70
            DataTypes.UserConfiguration storage userConfig,
71
            DataTypes.ExecuteSwapParams memory params
72
       ) external {
73
            ExecuteTradeVars memory vars;
74
            vars.assetConfigCache[0] = assetConfig[params.shortAsset];
75
            vars.assetConfigCache[1] = assetConfig[params.longAsset];
76
77
            if (
78
                IERC20Upgradeable(params.shortAsset).allowance(address(this), address(vars.
                    assetConfigCache[0].swapAdapter)) < params.amount
79
            ) {
80
                IERC20Upgradeable(params.shortAsset).safeApprove(address(vars.
                    assetConfigCache[0].swapAdapter), type(uint256).max);
81
           }
82
            vars.receivedAmount = vars.assetConfigCache[0].swapAdapter.swap(params.
                shortAsset, params.longAsset, params.amount, params.data);
84
85
```

Listing 3.2: TradeLogic::executeTrade()

Recommendation Apply necessary rigorous validity checks on the untrusted user input. Also raise the community awareness of not giving token allowance to the ZeroexSwapAdapter contract.

Status This issue has been fixed in this commit: d90a0c1.

3.2 Accommodation of approve() Idiosyncrasies

ID: PVE-002Severity: LowLikelihood: Low

• Impact: Low

• Target: Multiple Contracts

• Category: Coding Practices [8]

• CWE subcategory: CWE-1126 [1]

Description

Though there is a standardized ERC-20 specification, many token contracts may not strictly follow the specification or have additional functionalities beyond the specification. In this section, we examine the approve() routine and analyze possible idiosyncrasies from current widely-used token contracts.

In particular, we use the popular stablecoin, i.e., USDT, as our example. We show the related code snippet below. On its entry of approve(), there is a requirement, i.e., require(!((_value != 0) && (allowed[msg.sender][_spender] != 0))). This specific requirement essentially indicates the need of reducing the allowance to 0 first (by calling approve(_spender, 0)) if it is not, and then calling a second one to set the proper allowance. This requirement is in place to mitigate the known approve()/transferFrom() race condition (https://github.com/ethereum/EIPs/issues/20#issuecomment-263524729).

```
194
195
        * @dev Approve the passed address to spend the specified amount of tokens on behalf
196
        * Oparam _spender The address which will spend the funds.
197
        * @param _value The amount of tokens to be spent.
198
        */
199
        function approve(address spender, uint value) public onlyPayloadSize(2 * 32) {
201
            // To change the approve amount you first have to reduce the addresses '
202
            // allowance to zero by calling 'approve(_spender, 0)' if it is not
203
            // already 0 to mitigate the race condition described here:
204
            // https://github.com/ethereum/EIPs/issues/20#issuecomment-263524729
205
            require(!(( value != 0) && (allowed[msg.sender][ spender] != 0)));
207
            allowed [msg.sender] [ spender] = value;
208
             Approval (msg. sender, _spender, _value);
209
```

Listing 3.3: USDT Token Contract

Because of that, a normal call to approve() with a currently non-zero allowance may fail. In the following, we use the Ledger::_depositReserve() routine as an example. This routine is designed to transfer tokens from depositor to Ledger contract. To accommodate the specific idiosyncrasy, for

each safeApprove() (line 806), there is a need to approve() twice: the first one reduces the allowance to 0; and the second one sets the new allowance.

```
798
        function _depositReserve(address user, address asset, uint256 amount) internal {
799
             DataTypes.AssetConfig memory assetConfigCache = assetConfig[asset];
800
             DataTypes.ReserveConfig storage reserve = _reserveConfig[asset];
802
804
             if (reserve.reinvestment != address(0)) {
805
                 if (IERC20Upgradeable(reserve.asset).allowance(address(this), reserve.
                     reinvestment) < amount) {
806
                     IERC20Upgradeable(reserve.asset).safeApprove(reserve.reinvestment, type(
                         uint256).max);
807
                 }
809
                 IReinvestment (reserve.reinvestment).checkpoint (user, currUserReserveBalance)
810
                 IReinvestment(reserve.reinvestment).invest(amount);
811
812
                 reserve.liquidSupply += amount;
813
            }
815
             emit DepositedReserve(user, asset, reserve.reinvestment, amount);
816
```

Listing 3.4: Ledger::_depositReserve()

Recommendation Accommodate the above-mentioned idiosyncrasy about ERC20-related approve().

Status This issue has been fixed in this commit: d90a0c1.

3.3 Trust Issue of Admin Keys

• ID: PVE-003

Severity: Medium

Likelihood: Medium

• Impact: Medium

• Target: Ledger

• Category: Security Features [7]

• CWE subcategory: CWE-287 [3]

Description

In the LeverFi protocol, there is a privileged owner account that plays a critical role in governing and regulating the system-wide operations (e.g., system parameter setting and funds withdrawn in emergency). It also has the privilege to control or govern the flow of assets managed by this protocol.

Our analysis shows that the privileged account needs to be scrutinized. In the following, we examine the privileged account and their related privileged accesses in current contracts.

```
718
        function emergencyWithdrawReserve(address asset) external onlyOperator {
719
720
721
             DataTypes.ReserveConfig storage reserveConfig = _reserveConfig[asset];
722
723
             require(reserveConfig.state == DataTypes.AssetState.Disabled, "cannot withdraw
                 with active pool");
724
             require(reserveConfig.reinvestment != address(0), "reinvestment is not set");
725
726
             uint256 withdrawn = IReinvestment(reserveConfig.reinvestment).emergencyWithdraw
727
728
             reserveConfig.liquidSupply = withdrawn;
729
             emit EmergencyWithdrawnReserve(asset, withdrawn);
730
731
732
```

Listing 3.5: Ledger::emergencyWithdrawReserve()

If the privileged owner account is a plain EOA account, this may be worrisome and pose counterparty risk to the exchange users. Note that a multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed DAO. In the meantime, a timelock-based mechanism can also be considered as mitigation. Moreover, it should be noted if current contracts are to be deployed behind a proxy, there is a need to properly manage the proxy-admin privileges as they fall in this trust issue as well.

Recommendation Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been confirmed.

3.4 Necessity of Single-Shot Initialization of AaveReinvestmentLogic

• ID: PVE-004

Severity: CriticalLikelihood: High

• Impact: High

• Target: Multiple Contracts

Category: Initialization and Cleanup [12]

• CWE subcategory: CWE-1188 [2]

Description

The LeverFi protocol's collateral and reserve are deposited to farming protocols, allowing traders to earn yields and leverage trade at the same time. The reinvestment logic are implemented via the AaveReinvestmentLogic contract, which has an initialize() function. This function is used to initialize a number of key parameters, including asset, addressStorage, addressStorage, treasury, ledger and feeMantissa. To facilitate our discussion, we show below the related code snippet.

```
38
        function initialize(
39
            address asset_,
40
            address receipt_,
41
            address platform_,
42
            address[] memory,
43
            address treasury_,
44
            address ledger_,
45
            uint256,
46
            bytes memory
47
        ) public {
48
            asset = asset_;
49
            addressStorage[RECEIPT] = receipt_;
50
            addressStorage[PLATFORM] = platform_;
51
            treasury = treasury_;
52
            ledger = ledger_;
54
            // Fees does not applied to this type of reinvestment (auto-accruing reward).
55
            feeMantissa = 0;
56
```

Listing 3.6: AaveReinvestmentLogic::initialize()

Apparently the above logic does not provide the guarantee that the initialize() function can be called only once. What's more, it allows anyone to call the function! A bad actor could call initialize() and set the ledger to his own address, hence transferring all the tokens from the pool to his own wallet. Since multiple initializations could cause critical risk for the entire protocol, we suggest to ensure that the initialize() routine may only be called once.

```
function divest(uint256 amount) external override onlyLedger {
```

Listing 3.7: AaveReinvestmentLogic::divest()

Note another contract ConvexReinvestmentLogic shares the same issue.;

Recommendation Ensure the initialize() function could only be called once during the entire lifetime.

Status This issue has been fixed in the commit: 1d52714.

3.5 Reentrancy Risk in Ledger

• ID: PVE-005

Severity: Low

• Likelihood: Low

• Impact: Low

• Target: Ledger

• Category: Time and State [10]

• CWE subcategory: CWE-663 [4]

Description

A common coding best practice in Solidity is the adherence of checks-effects-interactions principle. This principle is effective in mitigating a serious attack vector known as re-entrancy. Via this particular attack vector, a malicious contract can be reentering a vulnerable contract in a nested manner. Specifically, it first calls a function in the vulnerable contract, but before the first instance of the function call is finished, second call can be arranged to re-enter the vulnerable contract by invoking functions that should only be executed once. This attack was part of several most prominent hacks in Ethereum history, including the DAO [17] exploit, and the recent Uniswap/Lendf.Me hack [16].

We notice there is an occasion where the <code>checks-effects-interactions</code> principle is violated. Using the <code>Ledger</code> as an example, the <code>executeShorting()</code> function (see the code snippet below) is provided to externally call a reinvestment contract to transfer assets. However, the invocation of an external contract requires extra care in avoiding the above <code>re-entrancy</code>.

Apparently, the interaction with the external contract (line 169) starts before effecting the update on the internal state (lines 185-193), hence violating the principle. In this particular case, if the

external contract has certain hidden logic that may be capable of launching re-entrancy via the same entry function.

```
156
     function executeShorting(
157
         DataTypes.ReserveConfig storage reserveConfig,
         DataTypes.AssetConfig memory assetConfigCache,
158
         DataTypes.UserPosition storage userAssetPosition,
159
160
         {\tt DataTypes.UserConfiguration} \ \ {\tt storage} \ \ {\tt userConfig} \ ,
161
         uint256 amount,
162
         bool doDivest
    ) public returns (uint256, uint256){
163
164
         ExecuteShortingVars memory vars;
165
166
         if (doDivest) {
167
             if (vars.amountLongToDivest > 0) {
168
                 if (assetConfigCache.longReinvestment != address(0)) {
169
                      IReinvestment (assetConfigCache.longReinvestment).divest (vars.\\
                          amountLongToDivest);
170
                 }
             }
171
172
             if (vars.amountToShort > 0) {
173
                 if (reserveConfig.reinvestment != address(0)) {
174
                      IReinvestment(reserveConfig.reinvestment).divest(vars.amountToShort);
175
                 } else {
176
                      reserveConfig.liquidSupply -= vars.amountToShort;
177
                 }
178
                 reserveConfig.scaledUtilizedSupplyRay += vars.amountToShort.unitToRay(vars.
                      unit).rayDiv(vars.reserveCache.currBorrowIndexRay);
179
             }
180
         }
181
         require(
182
             IERC20Upgradeable(reserveConfig.asset).balanceOf(address(this)) >= amount,
183
             "not enough gathered amount to proceed"
184
         vars.newPosition = getNewPosition(
185
186
             assetConfigCache,
187
             userAssetPosition,
188
             DataTypes.UserPosition(amount, DataTypes.PositionType.Short),
189
             {\tt vars.reserveCache.currBorrowIndexRay}
190
191
         userAssetPosition.amount = vars.newPosition.amount;
192
         userAssetPosition._type = vars.newPosition._type;
193
         userConfig.setUsingPosition(reserveConfig.assetId, vars.newPosition.amount > 0);
194
         return (amount, vars.amountToShort);
195 }
```

Listing 3.8: TradeLogic::executeShorting()

Note this is a protocol level issue and other routines share the same issue.

Recommendation Apply necessary reentrancy prevention by utilizing the nonReentrant modifier to block possible re-entrancy.

Status The issue has been fixed by this commit: 0b1f186.

3.6 Manipulated Utilized Supply For Inflated Reserve Balance

• ID: PVE-006

• Severity: Critical

• Likelihood: High

• Impact: High

• Target: Ledger

• Category: Time and State [11]

• CWE subcategory: CWE-682 [5]

Description

As mentioned in Section 3.4, the LeverFi protocol's reserve are deposited to farming protocols. During the audit, we notice there is a logic error in the computation for reserve supply. It could be exploited to get more underlying tokens from the Ledger contract via simple deposit reserve and withdraw reserve operations. To elaborate, we list the related routines, including getReserveSupply(), _depositReserve() and _withdrawReserve() when user performs the deposit and withdrawal.

```
22
        function getReserveSupply(
23
            DataTypes.ReserveConfig storage reserve,
24
            DataTypes.AssetConfig memory assetConfig,
25
            bool claimable
26
        ) internal view returns (uint256 poolAmount) {
27
            if (!claimable) {
28
29
30
                poolAmount += getUtilizedSupply(reserve, assetConfig);
31
            }
32
33
34
            poolAmount += GeneralLogic.getReserveAvailableSupply(reserve);
35
       }
36
37
38
        function _depositReserve(address user, address asset, uint256 amount) internal {
39
40
41
42
            uint256 shareAmountRay = ShareBaseAccounting.getShareAmount(
43
                amount.unitToRay(unit),
44
                reserve.scaledTotalSupplyRay,
45
                reserve.getReserveSupply(assetConfigCache, true).unitToRay(unit)
46
            );
47
48
49
50
```

```
51
52
        function _withdrawReserve(address user, address asset, uint256 amount) internal {
53
54
            uint256 currReserveSupply = reserveConfig.getReserveSupply(assetConfigCache,
                false):
55
56
57
            scaledAmountToWithdrawRay = ShareBaseAccounting.getShareAmount(
58
                amount.unitToRay(unit),
59
                currScaledTotalSupplyRay,
60
                currReserveSupply.unitToRay(unit)
61
            );
62
63
64
```

Listing 3.9: getReserveSupply::getReserveSupply()/Ledger::_depositReserve()/Ledger::_withdrawReserve()

In particular, the share amount of the user reserve is calculated via the amount of deposited underlying tokens multiples scaledTotalSupplyRay and then divides currReserveSupply. However, currReserveSupply is calculated via getReserveAvailableSupply(), which only counts the underlying utilized supply on withdrawal, not deposit. In other words, the value of the currReserveSupply is inflated when user doing a withdrawal. A bad actor could artificially manipulate the utilized supply to a big number to drain all the funds in the pool.

Recommendation Make sure the deposit and withdrawal operations using the same reserve supply to compute the share.

Status This issue has been fixed in the following commit: 5ab558f.

3.7 Exposure Of Permissioned Ledger::swapPosition()

ID: PVE-007

• Severity: Medium

• Likelihood: High

• Impact: Medium

• Target: Ledger

• Category: Business Logic [9]

• CWE subcategory: CWE-841 [6]

Description

The LeverFi protocol has a liquidator system in place to margin call traders if trading losses approach the value of collateral deposited. When examining the implementation of the liquidation system, we notice the presence of a specific routine, i.e., <code>swapPosition()</code>. As the name indicates, this routine is used to swap a position for the liquidation wallet. To elaborate, we show below the code snippet of this function.

```
1146
        function swapPosition(address assetIn, address assetOut, uint256 amount, bytes memory
            data) external {
1147
          TradeLogic.executeTrade(
1148
              _reserveConfig,
1149
              assetConfig,
1150
              _userPosition[LIQUIDATION_WALLET],
1151
              userConfig[LIQUIDATION_WALLET],
1152
              DataTypes.ExecuteSwapParams(
1153
                  LIQUIDATION_WALLET,
1154
                   treasury,
1155
                   assetIn,
1156
                   assetOut,
1157
                   amount,
1158
                   tradeFeeMantissa,
1159
1160
                  0,
1161
                  Ο,
1162
                  data,
1163
                  false,
1164
                  false
1165
              )
1166
          );
1167
```

Listing 3.10: Ledger::swapPosition()

However, we notice that this routine is currently permissionless, which means it can be invoked by anyone to update change the position to another one according to his wish. A bad actor could make profit by decreasing the PNL of the liquidation wallet while satisfy the requirement of int256(params.totalCollateralUsdPreLtv.wadMul(params.liquidationRatioMantissa))+ params.pnlUsd)>= 0.

Recommendation Adjust the modifier to constrain the operation of swapPosition() for the liquidation wallet.

Status This issue has been fixed in the following commit: 826f589.

4 Conclusion

In this audit, we have analyzed the LeverFi protocol design and implementation. LeverFi is a decentralized leveraged trading platforms which offers a leveraged solution for traders. During the audit, we notice that the current code base is well organized and those identified issues are promptly confirmed and fixed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
